## Why radio follow up of GWs?

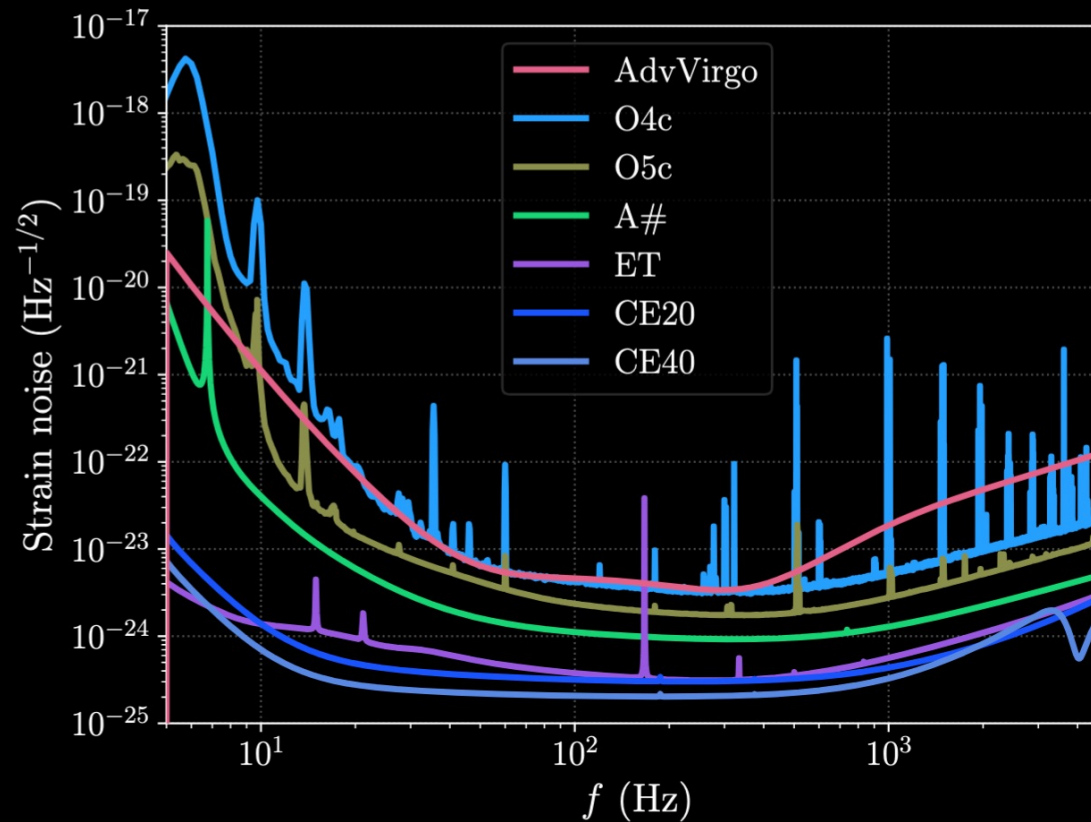

The **big picture** of the most cataclysmic cosmic events can only be made clear **when all messengers are gathered to probe progenitors, outflows, and remnants** in a holistic fashion.

Rubin LSST:  $\sim 10$  deg<sup>2</sup> FOV camera;  
8.4 m-diameter primary mirror;  
millions of alerts per night!  
( $\sim 2026$ )

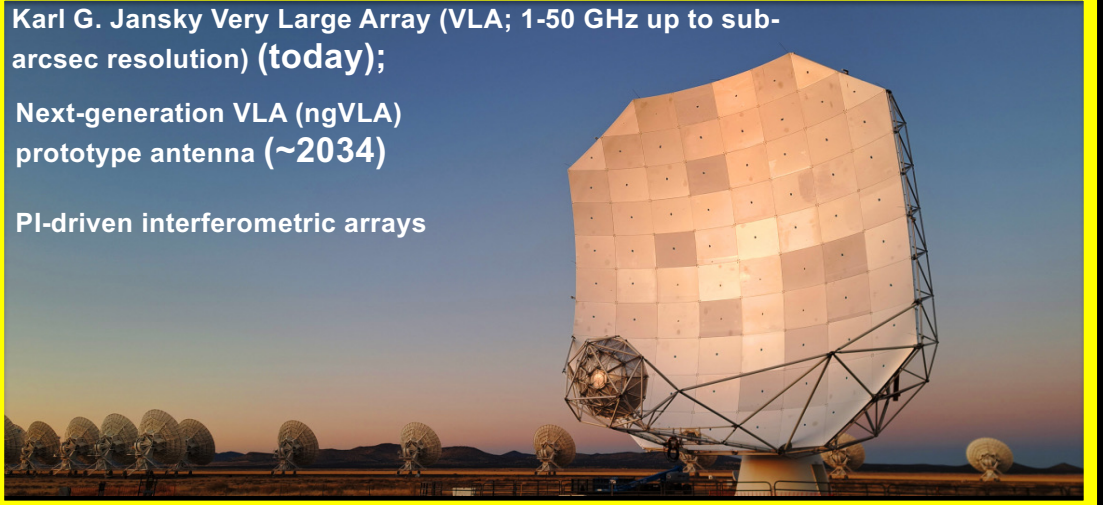

Argus Array: high-cadence, all-visible-sky survey  
imaging via 1,200 small-aperture telescopes with a  
combined collecting area equivalent to an 8-meter-  
class telescope ( $\sim 2028$ )

Karl G. Jansky Very Large Array (VLA; 1-50 GHz up to sub-arcsec resolution) (today);

Next-generation VLA (ngVLA)  
prototype antenna ( $\sim 2034$ )

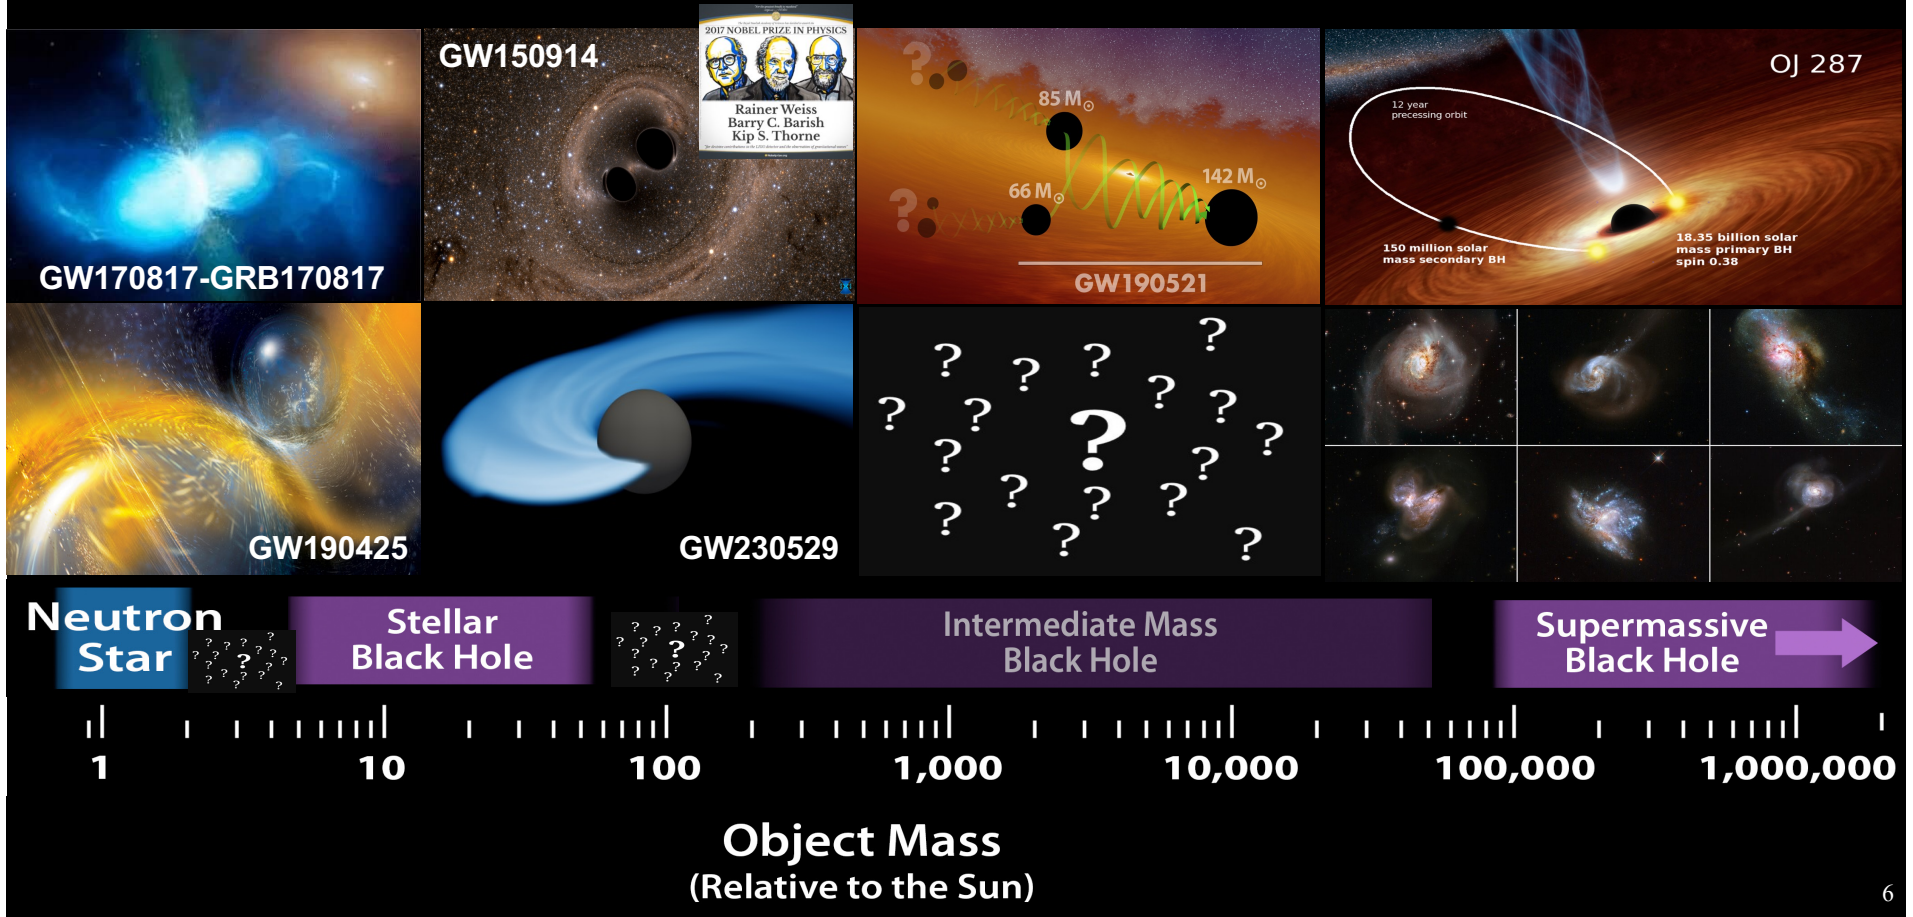

PI-driven interferometric arrays

DSA-2000 (0.7–2 GHz frequency; 3 arcsec resolution);  
wide-field, multi-epoch survey science ( $\sim 2029$ )

•Minor cycle: Peak-find and subtract the PSF in the image domain to build the sky model — fast but approximate.

## *CLEAN Imaging in CASA: gridding, FFT, and cycles*

### From visibilities to image

Adapted from:  
James Robnett

- Interferometers don't image directly, they sample the sky's Fourier transform (visibilities) at scattered (u,v) points (or tracks with Earth's rotation) set by each antenna pair.
- The FFT to the image needs a regular rectangular grid, but (u,v) sampling is not uniform.
- Gridding (which can be spread over multiple cores) convolves each visibility onto nearby grid cells; the gridded data are then FFT'd to produce the dirty (residual) image.
- Minor cycle: Peak-find and subtract the PSF in the image domain to build the sky model: fast but approximate
- Major cycle: Degrid the model, subtract from observed visibilities, re-grid to a fresh, accurate residual image.

# Challenges for CASA imaging apply to MMA

M. Lacy's talk and [https://casa.nrao.edu/casa\\_hardware-requirements.shtml](https://casa.nrao.edu/casa_hardware-requirements.shtml)

## File I/O

I/O-bound during gridding (major cycle) when data sits on a single disk is the major limitation of parallel CASA.

1× 6 TB Hard Disk Drive  
**~200 MB/s**

16-core node needs  
**400–800 MB/s**

Rule of thumb **25–50 MB/s per core**

*Tip — for data sets under 100 GB, SSDs are a cost-effective fix.*

## Memory

Two demands compete for RAM:

### Implicit **Filesystem cache**

RAM  $\geq$  data  $\rightarrow$  cached & fast. RAM  $<$  data  $\rightarrow$  disk. For 100 GB+, faster I/O beats more RAM.

### Explicit **Images**

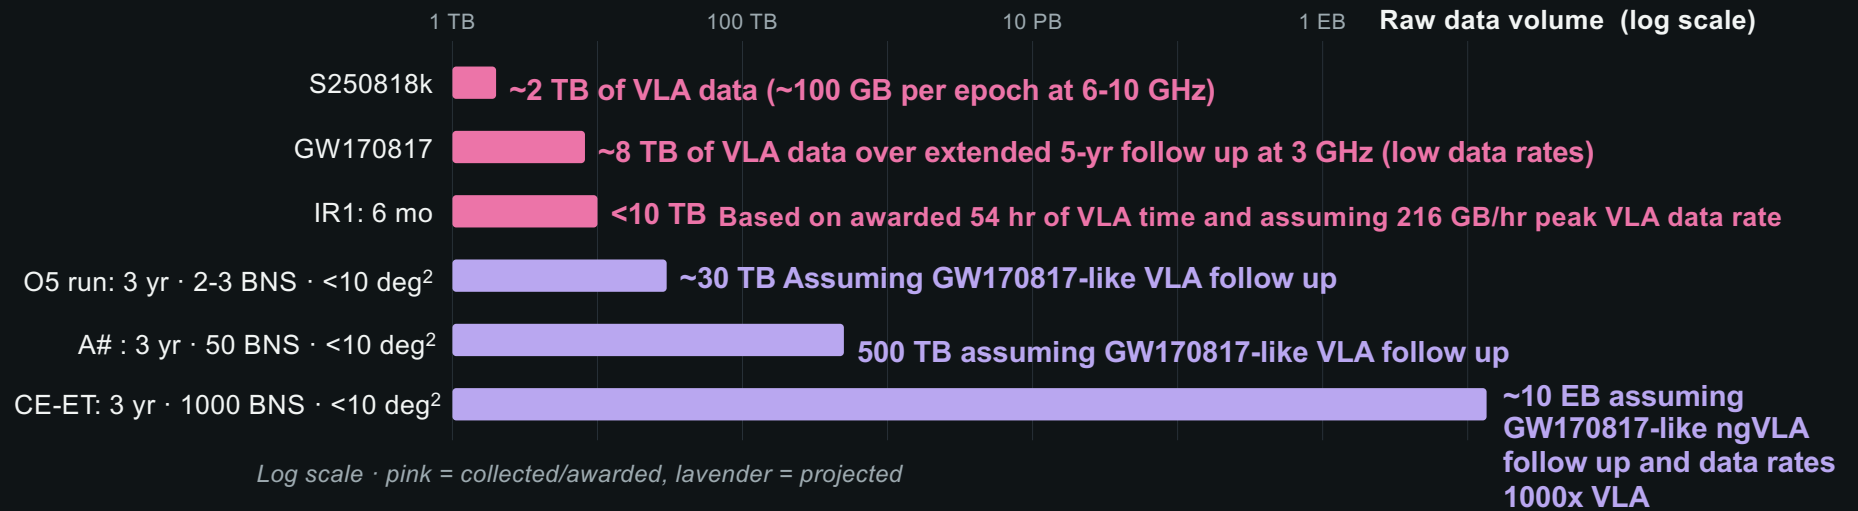

Must hold all intermediate minor-cycle images. Wide-band, wide-field, and newer algorithms need more.

**Too little  $\rightarrow$  swapping  $\rightarrow$  severe slowdown.**

**Bottom line:** Match I/O throughput and memory to your data-set size  
size I/O to core count · buy I/O speed before RAM for big data · keep RAM for all intermediate images.

# Evolution of the radio data volume for GW follow up (guesstimate)

Raw interferometric radio data per 3-year GW run: terabytes today (VLA), exabytes with the ngVLA

ngVLA avg data rate

**27 TB/hr**

peak 1.1 PB/hr · ~1000x VLA

Golden (<10 deg<sup>2</sup>) BNS / 3-yr run

**50 → 1000**

A# → CE-ET · <10 deg<sup>2</sup>, radio-followable

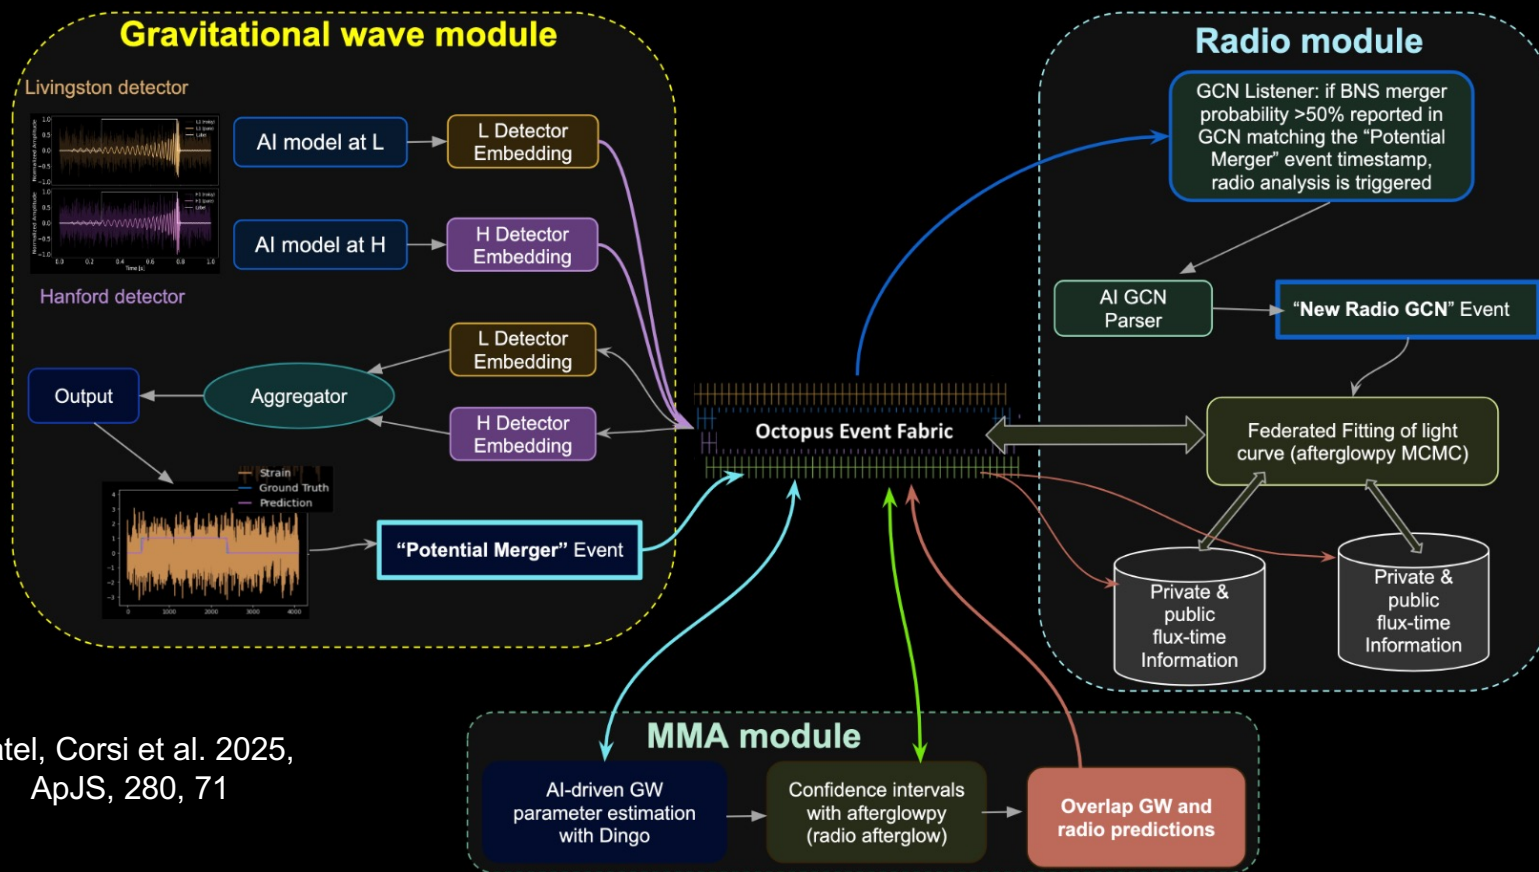

Science-ready data

**~1000x lighter**

than raw visibility data
