“the undiscussed problems” of...

Calibration and backgrounds via naive SIGNAL model

Consistent neglect of RESONANT processes

...and the revenge of the NEUTRON

Basic Misconceptions of Experimental Community I:

2.8 The Interaction of Neutrons

Techniques for nuclear and particle physics experiments:
a how-to approach By William R. Leo

Like the photon, the neutron lacks an electric charge, so that it is not subject to Coulomb interactions with the electrons and nuclei in matter. Instead, its principal means of interaction is through the strong force with nuclei. These reactions are, of course, much rarer in comparison because of the short range of this force. Neutrons must come within $\approx 10^{-13}$ cm of the nucleus before anything can happen, and since normal matter is mainly empty space, it is not surprising that the neutron is observed to be a very penetrating particle.

When the neutron does interact, however, it may undergo a variety of nuclear processes depending on its energy. Among these are:

- 1) Elastic scattering from nuclei, i.e., $A(n, n)A$. This is the principal mechanism of energy loss for neutrons in the MeV region.
- 2) Inelastic scattering, e.g., $A(n, n')A^*$, $A(n, 2n')B$, etc. In this reaction, the nucleus is left in an excited state which may later decay by gamma-ray or some other form of radiative emission. In order for the inelastic reaction to occur, the neutron must, of course, have sufficient energy to excite the nucleus, usually on the order of 1 MeV or more. Below this energy threshold, only elastic scattering may occur.

“neutron scattering is elastic 2-2...”

(just like wimps, but with smaller mass...)

...unless enough energy to excite a nuclear level...

Aside from the detector proposed in Ref. 5, an interesting possibility is to detect dark-matter particles via inelastic rather than elastic scattering from nuclei. For instance, ^{169}Tm has a $\frac{1}{2}^+$ ground state and a $\frac{3}{2}^+$ excitation at 8.4 keV. A dark-matter particle with $m \gtrsim 40$ GeV has enough kinetic energy to excite this transition. The excitation could readily be excited by particles like photinos with spin-dependent interactions. The signal would be the 8.4-keV x-ray photon from decay of the excited state,

Basic Misconceptions II:

“low energy cross sections are constant (in energy, angle, etc)” (not !)

Consider elastic scattering of halo particles of mass m by target nuclei of mass M . The elastic scattering cross section is $\sigma = [m^2 M^2 / \pi (m + M)^2] |\mathcal{M}|^2$, assuming the invariant amplitude \mathcal{M} is a constant (independent of angles) at low energy. If ρ is the mass density of halo parti-

M. Goodman and E. Witten, PRD 31,1985

...and so, theory models for *wimps* came to be used for estimating *reality*...

CALIBRATIONS!!

AFTER THAT, everyone's favorite
billiard ball model follows...

$$\Delta E \sim E_X \frac{2m_T m_X}{(m_T + m_X)^2} (1 - \cos\theta).$$

for 10 KeV, select the angle: $(1 - \cos\theta) \sim \frac{2m_T}{m_n} \frac{10\text{KeV}}{E_n} \rightarrow 0$

DAMA/LIBRA - calibrate at accelerator 2.45 MeV n beam

Chagani 'NaIrecoils' idm2006

CDMS - calibrate with 252 Cf source, MeV n peak

Phys.Rev.Lett.102:011301,2009, Phys.Rev.D66:122003,2002.

COGENT - calibrate with monochromatic n beam, 24 KeV

JCAP 0709:009,2007; NIM A 574 (2007) 385

P. Barnes, 96 Dissertation, early expressed:

“One line of defense against the muon-induced (underground) neutrons is to moderate the neutrons below detector threshold before they reach the detector. Note that an 18 KeV neutron has a maximum energy deposition on germanium of 1 KeV.”

(and THERMAL energy is defined as 0.024 eV)

famous quotations, in tiny font

while Ge and Si have similar scattering rates per nucleon for neutrons, Ge is 5–7 times more efficient than Si for coherently scattering WIMPs **CDMS Phys.Rev.D68:082002,2003**

As in the previous experiment, the propagation of these neutrons was simulated accurately, as confirmed by comparison with veto-coincident and calibration-source neutrons **CDMS Phys.Rev.Lett.102:011301,2009**

Over 600,000 events were recorded using the ^{252}Cf source during five separate periods throughout the runs, including more than 105 nuclear recoils used to characterize WIMP acceptance. **Phys.Rev.Lett.102:011301,2009**

Neutrons induced by radioactive processes or by cosmic-ray muons interacting near the apparatus can generate nuclear-recoil events that cannot be distinguished from possible dark matter interactions on an event-by-event basis. Monte Carlo simulations of the cosmic-ray muons and subsequent neutron production and transport have been conducted with FLUKA [13], MCNPX [14] and GEANT4 [15] to estimate this cosmogenic neutron background. **Phys.Rev.Lett.102:011301,2009**

Two methods are used to measure this flux of unvetted external neutrons. The first method involves comparing the rate of nuclear-recoil events in the Ge detectors

with the rate in the Si detector, since Ge is more sensitive to WIMPs and Si is more sensitive to neutrons.

The second method is to count the number of events consisting of nuclear recoils in two or more detectors **Phys.Rev.D66:122003,2002**.

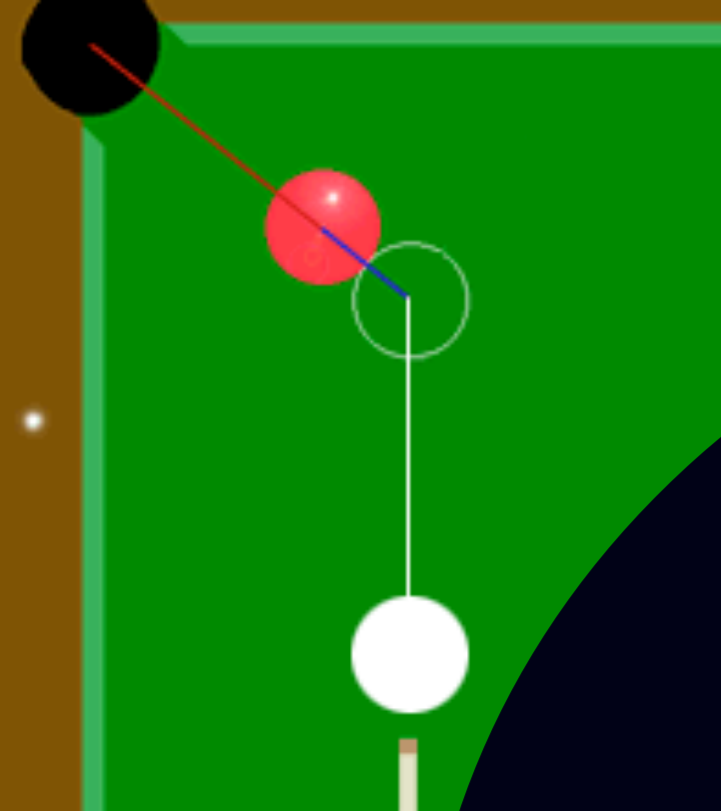

The energy deposited in the detector by an interacting particle is called “recoil energy” ER. If the particle interacts with an electron or electrons (e.g. by Compton scattering, K-capture, etc.), the event is called an electron recoil; if the particle interacts with a nucleus (e.g. by WIMP-nucleus or neutron-nucleus elastic scattering), the event is a nuclear recoil. Most of the recoil energy is converted almost immediately into phonons, **Phys.Rev.D66:122003,2002**.

In order to provide nuclear-recoil events that mimic WIMP interactions, a ^{252}Cf -fission neutron source is placed on the top face of the scintillator veto. Because the neutrons emitted by this source have such low energies (see e.g. [54]), the top layers of polyethylene inside the shield are removed to permit the neutrons to penetrate to the cryostat. With the source and shielding in this configuration, the data set is dominated by neutrons, making the total event rate about 3 times higher than during low-background data-taking. In all other ways, the data-taking conditions are as usual. The source activity is known to $\sim 5\%$ accuracy, so the absolute normalization of the spectrum is well determined **Phys.Rev.D66:122003,2002**.

For a low-mass WIMP, estimates of the neutron background have no effect **Phys.Rev.D66:122003,2002**.

Maybe all these problems
are well-known to a few experts
inside collaborations....

...but then why aren't they appearing in every
single conference talk and journal article?

(The business of backgrounds is not MY burden of proof)

Positive Suggestions

Why not calibrate everything all beams full energy range at accelerators, reactors, sources, multiples.

Stop assuming elastic recoil model for backgrounds

X-rays help calibrate sub-KeV region where hpge detectors perform for 30 years. $S/N \gg 1$. Why not try it?

Check out the limitations of GEANT, FLUKA, etc re: neutrons. Explore the unknowns of neutrons. There's less known than you think. And some of the known is junk

Current strategies are under-determined, hinge on "if not background we know, must be dark". Lame ! Develop over-determined multiple-detection consistency. DAMA has led strategy, but with gaps.

To control ubiquitous environmental annual effects, why not duplicate detector in southern hemisphere? It's only money.

Lead is a source of neutrons, almost the worst shield. Cd stops thermals, transmits $> eV$. Activation, Auger, internal conversion need to be divulged. Divulge !

Don't waste another workout! If you want to start gaining serious size, chug down some DARK MATTER and introduce your muscles to a new frontier of muscle growth as you enter the ANABOLIC AXIS. The biggest opportunity to stimulate muscle growth is immediately after your workout. The faster you can get critical nutrients into your bloodstream and muscles, the better. DARK MATTER employs new technologies and compounds which allow for the fastest possible nutrient uptake and sparks a synergistic anabolic reaction in which insulin levels simultaneously peak with amino acid, creatine and glycogen transport at the Anabolic Axis to trigger extreme muscle growth and speed recovery.

ProSYNTHAGEN™: Increases Protein Synthesis Faster Than Whey
ProSynthagen's unique combination of essential free form amino acids greatly stimulates protein synthesis faster than whey isolate. ProSynthagen isn't just fast, it's powerful too- each serving stimulates protein synthesis equivalent to 40 grams of protein. Additionally, ProSynthagen's amino acid matrix is fine-tuned with
