# Introduction

- Gravity can be **diluted** in the bulk (compactified extra dimensions).
- The momenta of the gravity field are **quantized**. (Kaluza-Klein modes).

We search for LED studying the exclusive **photon + missing transverse energy** channel.

# The distance hierarchy

$$M_{Pl}^2 = 8\pi M_D^{n+2} R^n$$

- $R$  = size of extra dimensions  
 $M_{Pl}$  = effective Planck scale in the 4D space-time  
 $M_D$  = fundamental Planck scale in the (4+n)D space time

**The hierarchy problem is solved (or actually, recast into a distance hierarchy problem)**

For  $M_D = 1$  TeV:

- $n = 1$ ,  $R \sim 10^{13}$  cm (solar system)  
 $n = 2$ ,  $R \sim 1$  mm  
 $n = 3$ ,  $R \sim 1$  nm  
 $n = 7$ ,  $R \sim 1$  fm (proton)

$$1 \text{ TeV}^{-1} \sim 10^{-19} \text{ m}$$

Signal process:

$$q\bar{q} \rightarrow \gamma + G_{KK}$$

- Generated using PYTHIA\* for  $n = 2$  to  $n = 8$ , at  $M_D = 1.5$  TeV.
- Kinematics independent of  $M_D$  for a fixed number of extra dimensions.
- The cross section in this case scales as  $1/M_D^{n+2}$

# D0 Detector

This analysis uses  
only the central region  
 $|\eta| < 1.1$

# Background sources and data samples

Physics Background:  $Z + \gamma \rightarrow \nu \bar{\nu} + \gamma$

An excess in events could also indicate the presence of anomalous  $ZZ\gamma$  couplings.

## Instrumental Backgrounds:

*large cosmic muons + halo particles background (non-collision)*

$W \rightarrow e \nu$                       *Electron misidentified as a photon*

$W + \gamma \rightarrow l \nu + \gamma$               *Lepton is lost*

$W/Z + \text{jet production}$               *Jet misidentified as a photon*

## Selection:

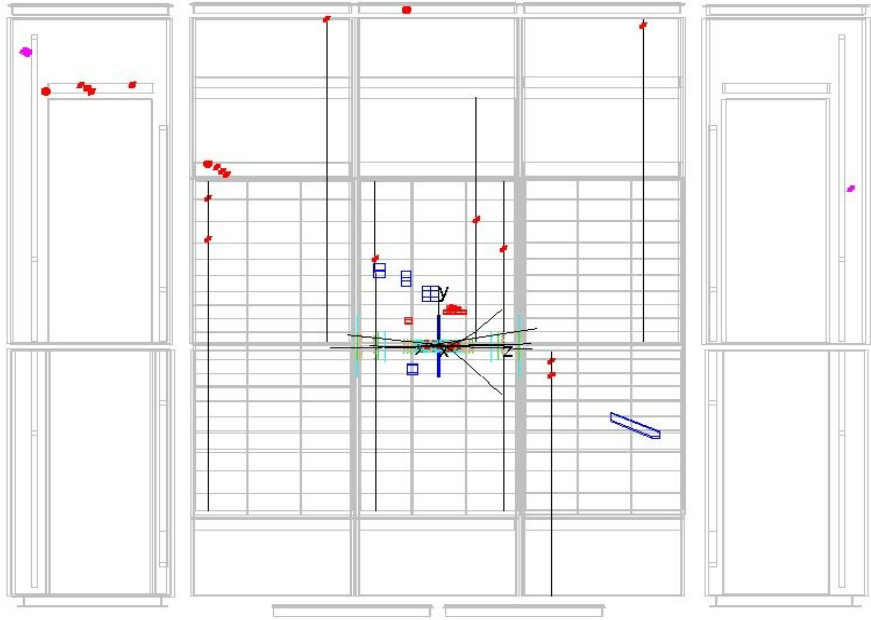

We prepare the **PHOTON SAMPLE** by selecting events with:

- Only one central photon with  **$p_T > 90 \text{ GeV}$**  (cluster isolated in the calorimeter and tracker, no track matched to it; topological cuts applied to reduce non-collision background.)
- Missing transverse energy  **$MET > 70 \text{ GeV}$**  (no multijet background)
- No jets with  **$p_{T, \text{jet}} > 15 \text{ GeV}$** .
- No events with reconstructed muons, with cosmic ray muons, or energetic isolated tracks.

**“FAKES” SAMPLE:** the isolation in the tracker is reversed

# Event display of a cosmic ray event

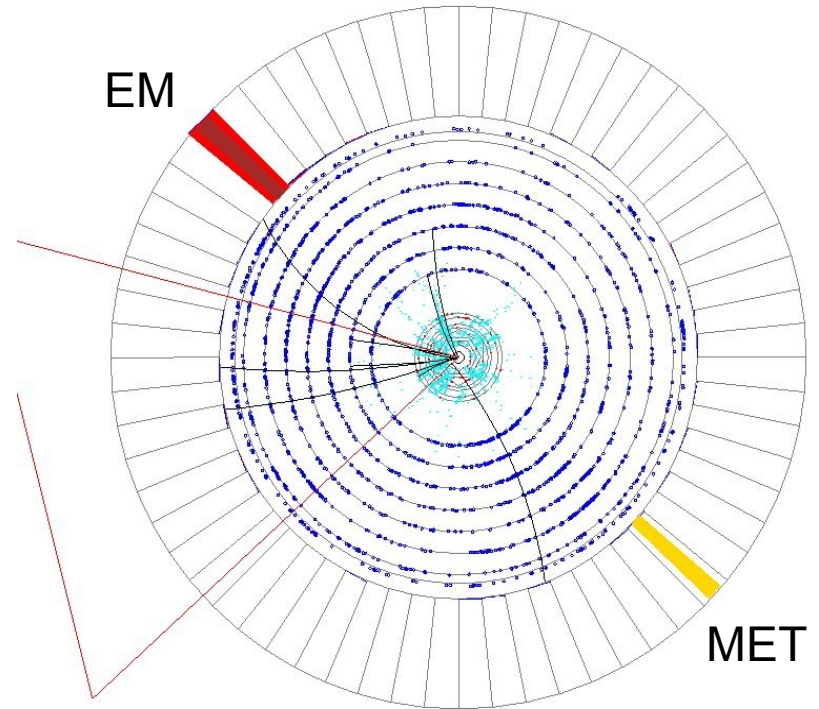

Run 210645 Evt 76850383

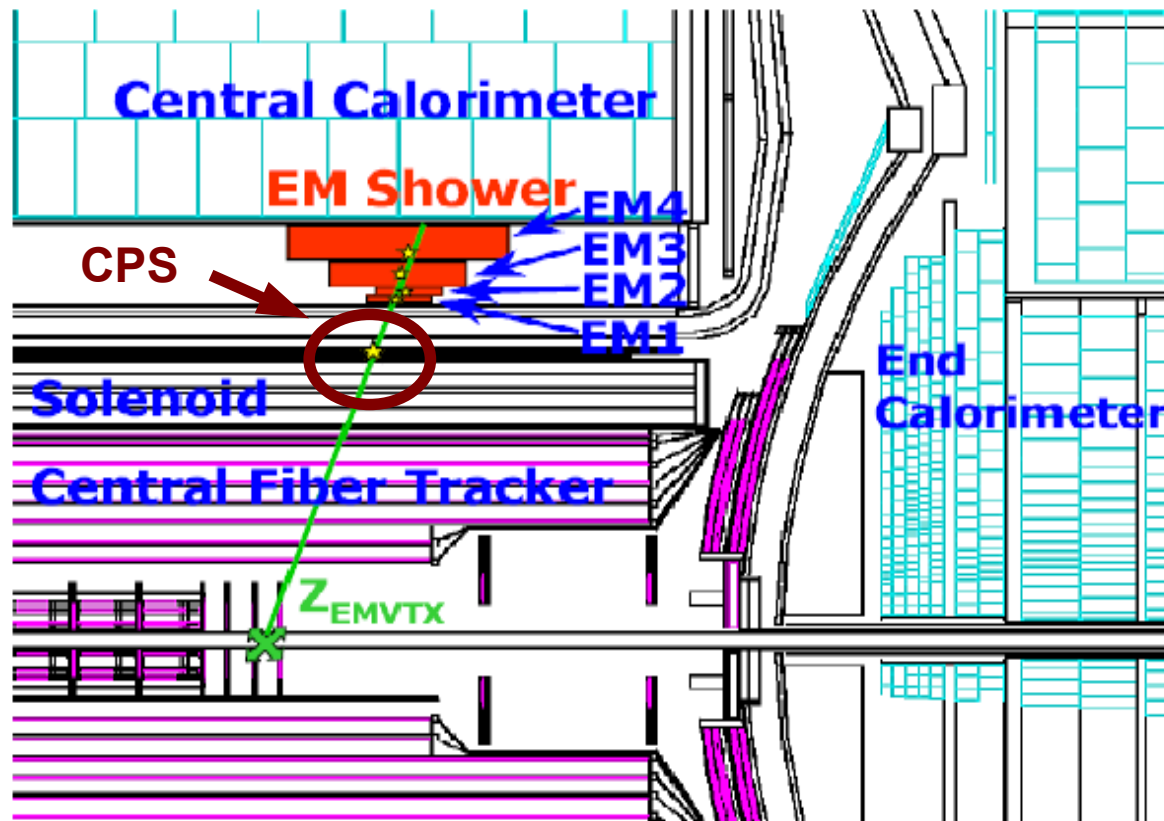

View 2, Side (Z-Y)

Run 210645 Evt 76850383

ET scale: 215 GeV

# EM Pointing Algorithm

**POINTING**: calculation of the direction of the EM shower based solely on the central preshower (CPS) and EM calorimeter clusters.

POLAR plane: **z position of vertex**

AZIMUTHAL plane : distance of closest approach to the beam line (**DCA**)

# Template construction for additional contributions

- **non-collision template:**  
(cosmics + halo)  
extracted from a sample with same kinematic cuts as for photon sample but requiring cosmics ray muons + events with no primary vertex or that have number of tracks  $< 3$
- **misidentified jets template:**  
extracted from the fake photon sample
- **$e/\gamma$  template:**  
extracted from a real data sample of isolated electrons and clean photons from data.

# Template construction for additional contributions

- **non-collision template:**

(cosmics + halo)  
extracted from a sample with same kinematic cuts as for photon sample but requiring cosmics ray muons + events with no primary vertex or that have number of tracks  $<$

- **misidentified jets template:**

extracted from the false photon sample

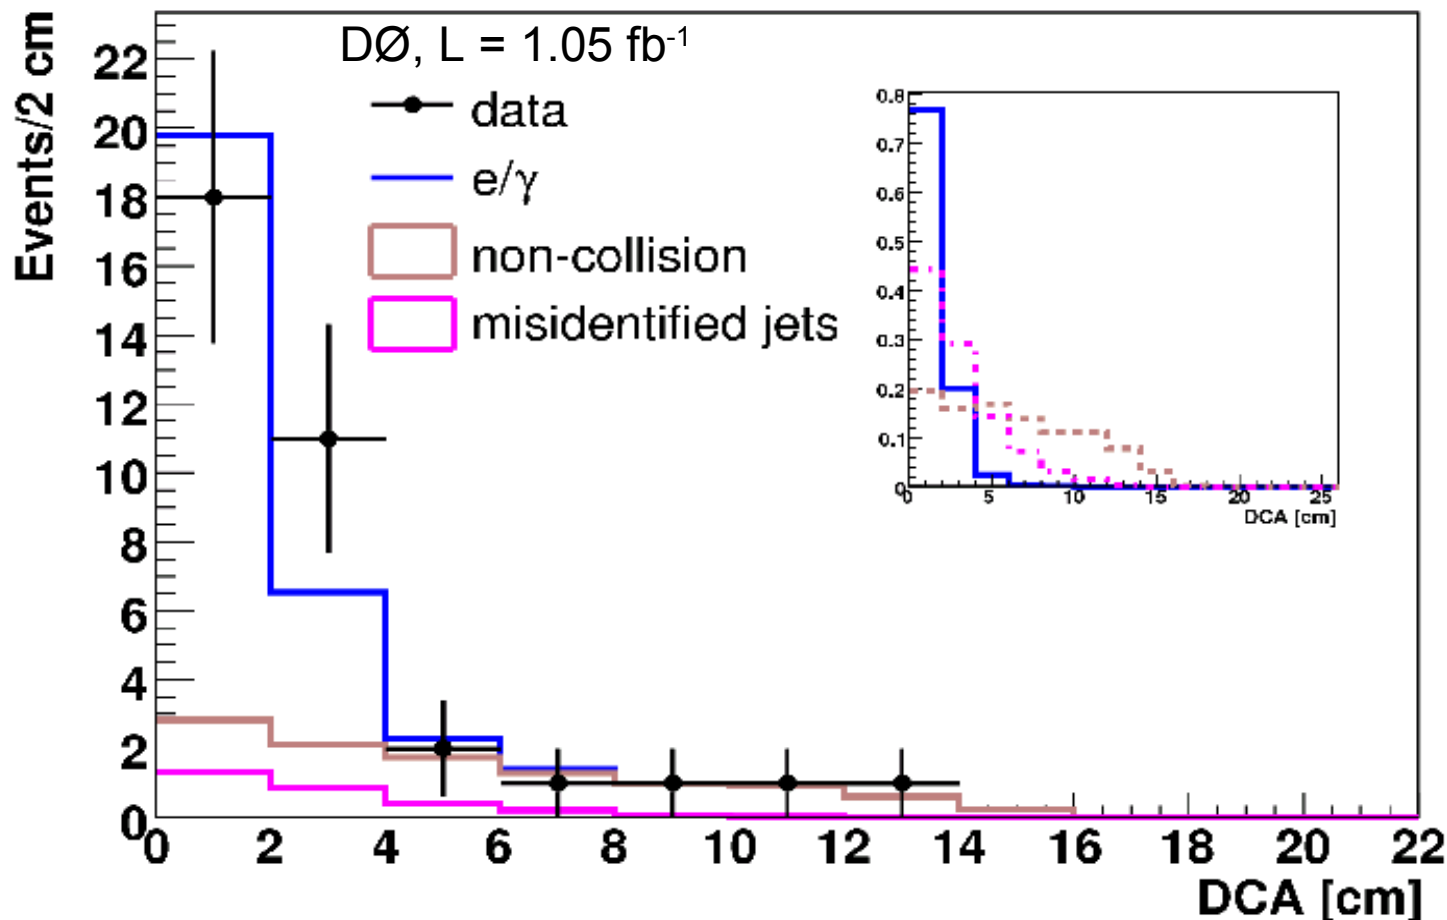

- **$e/\gamma$  template:**

extracted from a real data sample of isolated electrons and clean photons from data.

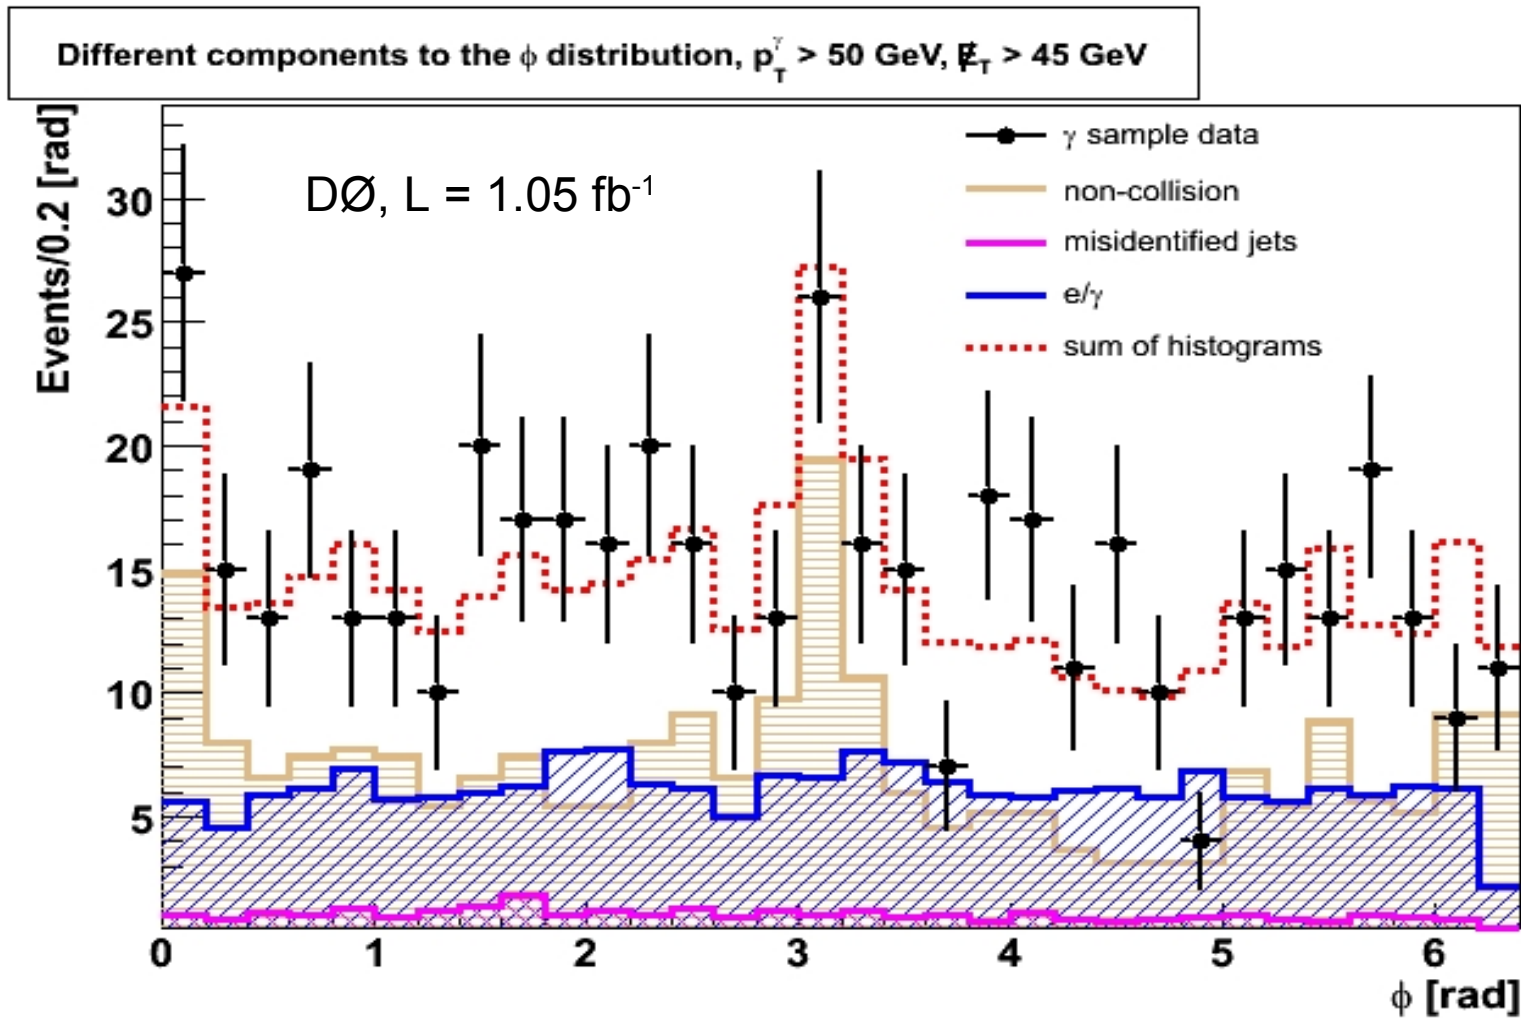

# DCA template fit

We fit the photon sample DCA distribution to a linear sum of the three templates fixing the contribution of misidentified jets from the rate of these objects in a photon + jet events, and determine the  $e/\gamma$  and non-collision contributions.

# Photon Sample – Azimuthal distribution

# Final counts and systematics

These numbers are **based on the first 2 bins in the DCA fit** plot which practically contain all prompt photons.

TABLE I: Data and estimated backgrounds.

Background	Number of expected events	
$Z + \gamma \rightarrow \nu\bar{\nu} + \gamma$	$12.1 \pm 1.3$	} from MC
$W + \gamma$	$1.5 \pm 0.2$	
$W \rightarrow e\nu$	$3.8 \pm 0.3$	} from DATA
Non-collision	$2.8 \pm 1.4$	
Misidentified jets	$2.2 \pm 1.5$	
Total Background	$22.4 \pm 2.5$	
Data	29	

Signal ACCEPTANCE x EFFICIENCY: ~ 50%

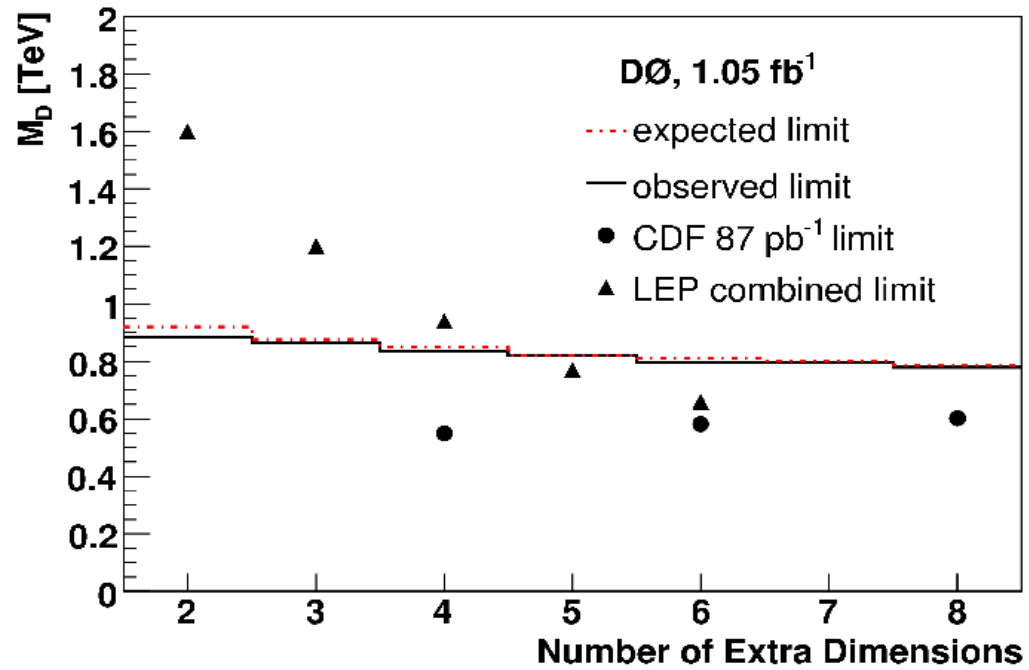

SYSTEMATICS: dominated by

- 5% **photon ID**,
- 6.1% **total integrated luminosity**,
- 4% **PDF** uncertainty.
- For MC SM backgrounds, 7% **k-factors**.

# Limits

We use a method based on log-likelihood ratio test statistic (**modified frequentist approach**) to calculate the limits on  $M_D$ . We use the binned photon  $p_T$  distribution.

**Photon  $p_T$  distribution** for the final candidate events, after all the applied requirements. The LED signal is stacked on top of the SM backgrounds.

# Summary and Conclusions

- Data and SM agree. We do not see any significant excess of events.
- No Large Extra Dimensions discovery :-)
- We set limits on the reduced Planck scale for number of dimensions 2 to 8. We improve latest CDF published limits ( $n > 4$ ) and LEP combined limits for  $n > 5$ .
- arXiv:0803.2137v1 [hep-ex], submitted to PRL.
- This analysis is being updated to include more data.

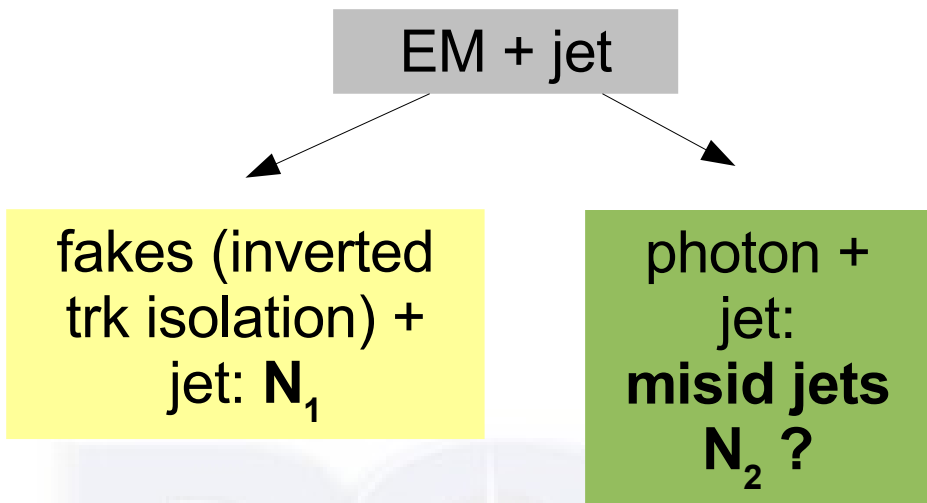

# Backup slides

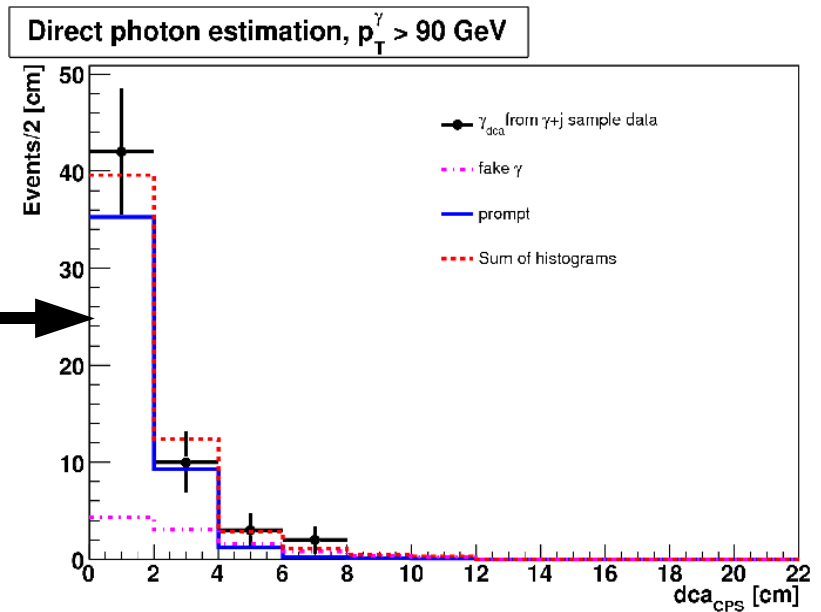

# Misidentified jets (fakes) normalization

- photon sample: has background events from misidentified jets ( $N_{\text{fake}}$ )
- fakes sample (inverted track isolation): known number of events  $N_0$

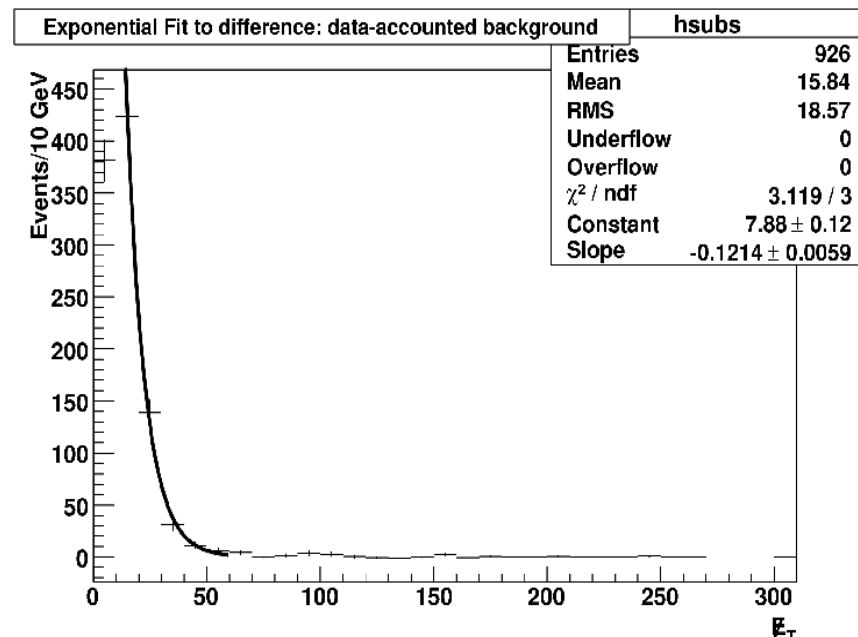

$$N_{\text{fake}} = N_0 \times (N_2 / N_1)$$

# QCD background

- We discard QCD or any other source of background for events with  $\text{MET} > 70$  GeV by performing an exponential fit on the difference: data – accounted background, after releasing the MET cut in the analysis.

MET distribution,  $p_T^\gamma > 90$  GeV

**There are no extra backgrounds after requiring  $\text{MET} > 70$  GeV.**

# Shapes comparison

DCA shapes comparison
