Radiative Corrections to the Higgs Boson Mass

 The mass of the Higgs field is not stable against radiative corrections:

- Little hierarchy problem [LEP paradox] [Barbieri and Strumia, 2000]:
 - The mass of Higgs boson is less than 250 GeV.
 - The cutoff Λ of relevant higher-dimensional operators must be greater than 5-10 TeV.

Little Higgs Model [Arkani-Hamed, Cohen and Georgi, 2001]

- Identify the Higgs doublet as a pseudo-Nambu-Goldstone boson (PNGB) of a spontaneously broken global symmetry.
- Collective Symmetry Breaking: two or more couplings are needed to explicitly break the global symmetry.
- Consequence: only logarithmically divergent potentials of the Higgs doublet are generated at one-loop level. The weak scale can be protected up to 5-10 TeV.

Cancellations in the gauge sector:

- Gauge symmetries in various little Higgs models [SU(3)_c is not included]:
 - The minimal moose model: $SU(3) \times SU(2) \times U(1)$.
 - The littlest Higgs model: [SU(2) × U(1)]².
 - The simplest little Higgs model: $SU(3) \times U(1)$.
- Predict Z', W'; t' and partners of other light quarks; extra scalars including triplets and singlets.

Simplify Little Higgs Model

 How about the most minimal extension of the standard model gauge group: SU(2) × U(1) × U(1)?

• What is the symmetry for this cancellation?

Observations

The field content under the gauge symmetry:

The kinetic terms of scalars:

 $\sin^2 \theta_W = a'^2/(a^2 + a'^2) \approx 0.23$

$$|(\partial_{\mu} + ig \, t^a \, W_{\mu}^a + i \frac{g'}{2\sqrt{2}} (B_{1\mu} + B_{2\mu}))H|^2 + |(\partial_{\mu} + i \frac{5g'}{3\sqrt{2}} (B_{1\mu} - B_{2\mu}))S|^2$$

• A Z_2 interchanging symmetry: $g_1 = g_2 = \sqrt{2}g'$

g' is the gauge coupling of $U(1)_Y$; g is the gauge coupling of $SU(2)_W$.

The Λ² contributions to scalar masses from gauge bosons are:

$$\begin{array}{lcl} V_g & = & \frac{3\,\Lambda^2}{64\pi^2} \left[(3g^2\,+\,g'^2) H H^\dagger + \frac{100}{9} g'^2 S S^\dagger \right] \,+\, \cdots\,, \\ \\ & \approx & \frac{25g'^2\Lambda^2}{48\pi^2} \left[H H^\dagger + S S^\dagger \right] \,\propto\, \phi\,\phi^\dagger \Rightarrow \text{Approximate U(3)$ global symmetry} \end{array}$$

Nonlinear Realization

- Write *H* and *S* together as a triplet of U(3): $\phi = (H, S)^T$
- $\langle \phi \rangle = (0, 0, f)^T$ from underlying dynamics

global symmetry:
$$U(3) \rightarrow U(2)$$
 gauge symmetry: $SU(2)_w \times U(1)_1 \times U(1)_2 \rightarrow SU(2)_w \times U(1)_Y$

- Below the cutoff $\Lambda \approx 4\pi f$, the EFT contains 9-4=5 GB's.
 - One is eaten by the massive neutral gauge boson: $B' \equiv (B_1 B_2)/\sqrt{2}$
 - The other 4 become PNGB's and identified as the Higgs doublet: h

$$\phi^T = f(\frac{ih}{\langle h \rangle} \sin \frac{\langle h \rangle}{f}, \cos \frac{\langle h \rangle}{f}) = (ih, f - \frac{\langle h \rangle^2}{2f}) + \cdots$$

The field dependent masses of gauge bosons are:

$$M_W^2(h) = c_W^2 \, M_Z^2(h) = {1\over 2} g^2 f^2 \sin^2 {\langle h
angle} \over f \, M_{B'}^2(h) = {50\over 9} g'^2 f^2 \cos^2 {\langle h
angle} \over f \,$$

Calculate the one-loop effective potential

$$V_{CW} = rac{3}{32\pi^2} \, \Lambda^2 \, {
m Tr}[M_g^2] \, - \, rac{3}{64\pi^2} {
m Tr}[M_g^4 \log{(rac{\Lambda^2}{M_g^2} \, + \, rac{3}{2})}]$$

• The Higgs mass contributions from the gauge sector:

$$\textit{m}_{h}^{2}|_{\textit{g}} = \tfrac{3g'^{2}\Lambda^{2}}{32\pi^{2}}\big(\tfrac{27-118s_{w}^{2}}{9s_{w}^{2}}\big) + \tfrac{3\textit{M}_{B'}^{4}}{32\pi^{2}\textit{f}^{2}}\big(log\,\tfrac{\Lambda^{2}}{\textit{M}_{B'}^{2}} + 1\big)$$

• For s_w^2 around 0.23, the Λ^2 term is even smaller than $\log \Lambda$ term

(Approx.
$$U(3)$$
 symmetry)

$$m_h^2|_q \approx -(87 \ GeV)^2 + (116 \ GeV)^2$$
,

for
$$f = 800 \text{ GeV}$$
, $\Lambda = 10 \text{ TeV}$, $s_w^2 = 0.23$.

Z₂ Broken Model

• The field content under the gauge symmetry:

	$SU(3)_c$	$SU(2)_W$	$U(1)_1$	$U(1)_2$
Н	1	2	1/2	1/2
S	1	1	5/3	-5/3
q_L	3	2	1/6	1/6
t_R	3	1	2/3	2/3
b_R	3	1	-1/3	-1/3
ψ_{L}	3	1	7/3	-1
ψ_{R}	3	1	7/3	-1

Only a colored vector-like quark added; gauge anomalies are still cancelled.

• The Yukawa couplings in the top sector are:

$$\mathcal{L}_t = y_1(\bar{q}_L, \bar{\psi}_L) \phi t_R + y_2 f \bar{\psi}_L \psi_R = y_1(\bar{q}_L \tilde{H} + \bar{\psi}_L S) t_R + y_2 f \bar{\psi}_L \psi_R + h.c.$$

$$Z_2 \text{ symmetry is manifestly broken}$$

Z₂ Broken Model

• Higgs boson masses from the top sector:

$$m_h^2|_t = -\frac{3}{8\pi^2}y_t^2 m_{t'}^2 (\log \frac{\Lambda^2}{m_{t'}^2} + 1)$$

No Λ^2 contribution: collective breaking mechanism protects it.

Spontaneously electroweak symmetry breaking:

$$m_h^2 = m_h^2|_g + m_h^2|_t < 0$$

Minimizing the full potential, we get a light Higgs boson below 200 GeV.

• Spectrum:
$$m_t = y_t \langle h \rangle$$
 $y_t = \frac{y_1 y_2}{\sqrt{y_1^2 + y_2^2}}$ $m_{t'} = \sqrt{y_1^2 + y_2^2} f$

$$t_{L,m} \approx t_L$$
 $t_{R,m} \approx (y_2 t_R - y_1 \psi_R) / \sqrt{y_1^2 + y_2^2}$
 $t_I' \approx \psi_L$ $t_R' \approx (y_1 t_R + y_2 \psi_R) / \sqrt{y_1^2 + y_2^2}$

- Large mixing between the right-handed parts of t and t' quarks.
- Both Z and B' couple to t_R and t'_R with order one couplings.

Electroweak Precision Test

- At tree level, only the experimentally unmeasured top quark couplings to W and Z bosons are changed.
- At one-loop level, the strongest constraint comes from the T parameter:

$$\alpha T = \frac{3y_t^2 y_1^2 m_t^2}{16\pi^2 y_2^2 m_{t'}^2} (\log \frac{m_{t'}^2}{m_t^2} - 1 + \frac{y_1^2}{2y_2^2})$$

[From PDG, $\alpha T < 1.2 \times 10^{-3}$ at 95% confidence level for $m_h <$ 300 GeV.]

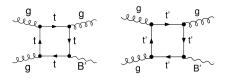

• For $y_1/y_2 < 3/4$, there is no bound on the symmetry breaking scale f. Hence, f can be as low as 400 GeV (to have the cutoff Λ above 5 TeV).

Signatures of the Z_2 Broken Model

- Two new parameters: y_2 and $f(y_1)$ is determined by y_2 and y_t).
- Predicts two new particles: B' and t'.

$$M_{B'} = 5\sqrt{2}g'f/3 \approx 0.8f$$
 $m_{t'} = \sqrt{y_1^2 + y_2^2}f \ge 2f$

- For $f \ge 400$ GeV, $M_{B'} \ge 300$ GeV. This possible light neutral gauge boson only couples to top quarks (nonuniversal).
- B' can mainly be produced through loop diagrams at Hadron Colliders like:[working in progress with Rakhi Mahbubani]

• B' decays to two top quarks. Mainly look for $t\bar{t}+1$ jet.

Z₂ Unbroken Model

- To have a cold dark matter candidate, we need to keep this \mathbb{Z}_2 to be unbroken to have stable particles. [Low and Cheng, 2003]
- Introduce two more vector-like quarks:

	$SU(3)_c$	$SU(2)_w$	$U(1)_1$	$U(1)_2$
Н	1	2	1/2	1/2
S	1	1	5/3	-5/3
q_{1_L}	3	2	1/6	1/6
t_R^{-}	3	1	2/3	2/3
b_R	3	1	-1/3	-1/3
ψ_{1_L}	3	1	7/3	-1 .
$\psi_{1_{R}}$	3	1	7/3	-1
$\psi_{2_L} \ \psi_{2_R} \ q_{2_L}$	3	1	-1	7/3
$\psi_{2_{R}}^{-}$	3	1	-1	7/3
q_{2i}	3	2	1/6	1/6
$q_R^{\prime^{\perp}}$	3	2	1/6	1/6

Gauge anomalies are cancelled.

Z_2 invariant

$$\mathcal{L}_{t} = \frac{y_{1}}{\sqrt{2}} (\bar{q}_{1_{L}} \tilde{H} + \bar{\psi}_{1_{L}} S) t_{R} + y_{2} f \bar{\psi}_{1_{L}} \psi_{1_{R}}$$

$$+ \frac{y_{1}}{\sqrt{2}} (\bar{q}_{2_{L}} \tilde{H} + \bar{\psi}_{2_{L}} S^{\dagger}) t_{R} + y_{2} f \bar{\psi}_{2_{L}} \psi_{2_{R}}$$

$$+ \frac{y_{3}}{\sqrt{2}} f (\bar{q}_{1_{L}} - \bar{q}_{2_{L}}) q'_{R} + h.c.$$

Under the Z_2 transformation, we have

$$Z_2: \qquad q_{1_L} \leftrightarrow q_{2_L}, \quad \psi_{1_{L,R}} \leftrightarrow \psi_{2_{L,R}}, \quad q_R' \to -q_R', \ B_1 \leftrightarrow B_2, \quad S \leftrightarrow S^\dagger$$
 and all other fields are invariant

Mass Spectrum

 Z_2 is exact; all particles are Z_2 eigenstates.

• Z₂ even particles:

t:
$$t_{L,m} \approx t_L$$
 $t_{R,m} \approx \frac{y_2 t_R - y_1 (\psi_{1_R} + \psi_{2_R})/\sqrt{2}}{\sqrt{y_1^2 + y_2^2}}$ $m_t = \frac{y_1 y_2}{y_1^2 + y_2^2} \langle h \rangle$
 t'_+ : $t'_{+L} \approx \frac{\psi_{1_L} + \psi_{2_L}}{\sqrt{2}}$ $t'_{+R} \approx \frac{y_1 t_R + y_2 (\psi_{1_R} + \psi_{2_R})/\sqrt{2}}{\sqrt{y_1^2 + y_2^2}}$ $m_{t'_+} \approx \sqrt{y_1^2 + y_2^2} f \ge 2 f$

The Λ^2 contribution to the Higgs mass from t is cancelled by t'_+ .

All other standard model particles are also Z_2 even.

Z₂ odd particles:

$$\begin{array}{lll} t'_{-}: & t'_{-L} \approx \frac{\psi_{1_{L}} - \psi_{2_{L}}}{\sqrt{2}} & t'_{-R} \approx \frac{\psi_{1_{R}} - \psi_{2_{R}}}{\sqrt{2}} & m_{t'_{-}} = y_{2} f \\ q'_{-}: & q'_{-L} \approx \frac{q_{1_{L}} - q_{2_{L}}}{\sqrt{2}} & q'_{-R} \approx q'_{R} & m_{q'_{-}} = y_{3} f \\ B': & (B_{1} - B_{2})/2 & M_{B'} \approx 0.8 f \end{array}$$

• For $y_2, y_3 \ge 1$, B' is the lightest Z_2 odd particle and a potential dark matter candidate in this model.

Dark Matter

• From WMAP, the relic abundance of the dark matter is:

$$0.098 < \Omega_{dm}h^2 < 0.122 (2\sigma)$$

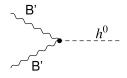

• In the non-relativistic limit, $\Omega_{dm}h^2$ is relating to sum of the quantities, $a(X) = v_r \sigma(B'B' \to X)$, as

$$\Omega_{dm} h^2 pprox rac{1.04 imes 10^9 \, \mathrm{GeV}^{-1}}{M_{pl}} rac{x_F}{\sqrt{g^*}} rac{1}{a_{tot}}$$

Approximately, only need to calculate a_{tot} and require:

$$a_{tot} \approx 0.81 \pm 0.09 \, pb$$

Couplings of B' to Higgs Boson

Minimal Little Higgs Model

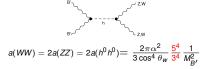

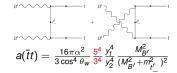

Hypercharge-like Gauge Boson [LHT and UED]

$$\frac{1}{2}g'^2v$$

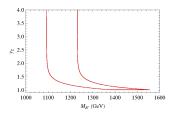

Relic Abundance

The leading processes for B' B' annihilation into SM particles:

For $y_2 \gg 1$, $a(\bar{t}t)$ is negligible.

$$[M_{B'} \approx 0.8 \, f \, m_{t'_{-}} = y_2 \, f]$$
 $0.098 < \Omega_{dm} h^2 < 0.122 \, (2\sigma) \Rightarrow a_{tot} \approx 0.81 \pm 0.09 \, pb$

Direct Detection

 Measure the recoil energy in the elastic scattering of dark matter particles with nuclei.

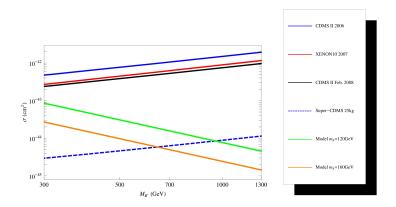

Only contribute to spin-independent cross section

 Using the matrix element of quarks and gluons in a nucleon state: [Ellis, Olive, Santoso, Spanos, 2005]

$$\sigma_{SI} \approx \tfrac{0.35^2\,g'^4}{16\pi\,M_{B'}^2} \tfrac{10^4}{3^4}\,\tfrac{m_p^4}{m_h^4} \approx 1.6\times 10^{-44} \text{cm}^2\,(\tfrac{1\,\text{TeV}}{M_{B'}})^2 (\tfrac{100\,\text{GeV}}{m_h})^4$$

 Box diagrams with the top quark propagating in the the loop also contribute to spin-dependent cross section.

Direct Detection

Summary

- A very simple little Higgs model has been constructed based on the $SU(2)_w \times U(1)^2$ gauge symmetry.
- A Z₂ interchanging symmetry is introduced between these two U(1)'s.
- For Z₂ broken case: only B' and t' appears in the EFT. The mass of B' can be as light as 300 GeV.
- For Z₂ unbroken case:
 - B' is a stable particle and can serve as a dark matter candidate.
 - The direct detection of this B' dark matter is promising.
 - The σ_{SI}(B'N) is two order of magnitude larger than a hypercharge-like neutral gauge boson dark matter candidate.
